Analysis

Overview

I am creating a free to play Texas hold 'em poker web application that can be played from any web browser with JavaScript. Existing products I have seen are Appeak Poker, an online poker app for IOS and Android. In this app a user can join different tables to play poker, add friends and keep track of their stats as they play, along with a total amount of money they have earned throughout their game time.

The Rules of Texas hold 'em

Pre-Game

One player acts as dealer. The dealer is represented by the player with the dealer button, and moves clockwise each round.

The game starts with two forced bets by the two players to the dealers left. These are called the small blind (SB) and the big blind (BB).

The SB is equal to the minimum bet. The BB is twice that of the small blind. After the blinds, play moves into the betting phase.

Play

Following the blinds, each player receives two cards face down. These are your 'hole' cards. The play continues clockwise, where each player following the blinds can either:

- **Call** – Calling matches the highest bet, in this cast the BB. If the highest current bet is 0 and the players calls, it is called a 'check'.
- **Raise** – A player can raise the bet up to the amount they have left on the table.
- **Fold** – By folding, a player is choosing not to continue betting and withdraws from the round.

The betting round continues until every player has put an equal amount of money in the pot or there is only one player left in the round. If a player calls or raises up to all of their money, they are said to have gone 'all-in', and a side-pot is created, which contains the pot which equates to the amount of chips the player has put in.

This means that the other players may continue to bet between themselves with the all-in player only eligible to win chips up to the amount he has put in.

Once the betting round has completed, three community cards are shown, known as 'the flop'. Community cards can be used by any player to make the best 5 card hand possible.

Another betting round then commences where the players have an option to call (or 'check' if no bet has been made), raise (or bet if a bet has been made) or fold. When the second betting round is finished, a fourth card is shown, known as 'the turn'.

Another betting round takes place, after which the final card is shown, known as 'the river' and after the final betting round if there are still two or more players left, the game goes to a showdown.

Showdown

If a player bets and all other players fold, the player is awarded the pot and is not required to show his cards. However, if there are still two or more players left after the final round of betting, a 'showdown' occurs, where the last player to bet is the first to show his hand, unless everyone checks in which case the player to the left of the dealer button is the first to show.

After the first player has shown his cards, the players must show their cards in a clockwise rotation if they can beat the best players hand to show. Otherwise they can choose not to show, and 'muck' their losing hand without showing them.

If two players have the same hand strength, 'kickers' can be used to break ties. These are extra cards that do not add to the rank of the hand.

For example, **K-K-10-3-2** would beat **K-K-9-8-7** even though they are both pairs of kings, as the **10** would beat the **9**. If the best hand is shared by two or more players, the pot is shared between them. If the pot cannot be equally distributed among all the players in the split pot, the odd chips are given precedence to the winners that are first to play.

Poker Hand Rankings

1. Royal Flush A, K, Q, J, 10 all of the same suit 	2. Straight Flush Any five card sequence in the same suit 
3. Four of a Kind All four cards of the same rank 	4. Full House Three of a kind combined with a pair 
5. Flush Any five cards of the same suit, but not in sequence 	6. Straight Five cards in sequence, but not in the same suit 
7. Three of a Kind Three cards of the same rank 	8. Two Pair Two separate pairs 
9. Pair Two cards of the same rank 	10. High Card Otherwise unrelated cards ranked by the highest single card 

Algorithms

I am using the Django framework for my web application because it is one of the most documented and versatile web app frameworks for Python. It is an extremely stable and scalable framework used by many large companies such as Instagram and Pinterest. I can also develop new features to add to the web app quickly, and add custom programs such as a python poker algorithm relatively easily as it is extremely customisable and written in the same language. I am using sqlite3 to manage the database for its ease of use and that it is the default database that ships with Django. The website will be hosted on my computer on port 8000 and can be accessed by any computer on the same network.

Supervisor

My supervisor is Archie McMullan who is a regular user of Appeak Poker, and so has some experience with online poker and products like this. Archie also has a good knowledge of Python so can understand the use cases and complexity of different objectives to give more informed feedback, for instance a poker ai algorithm would need to make decisions with only incomplete information, so to create an optimal poker ai is much harder than it sounds and is an area in current cutting edge research.

Archie suggested that the users could be shown around a table with their money, with the pot and cards in the middle of the table to make the game look more akin to real life poker. We also discussed getting card images of the internet, and show them pop up with animations instead of a text-based version of the game. Archie also suggested a friend feature on the app, in which you could see whether they are online and join their game. We thought that users could send friend requests to other users they are in a game with or by searching for their username on the friends page. He also suggested creating a leaderboard page so you could compete with other players with your total money.

My end users are people aged 16 and over who enjoy playing poker without having to commit any real money to the game.

Objectives

1. Players will be able to register with a username and password, and log in/out. The users account information is then stored in the database
2. A player's total money is stored in a database
 - a. On entering a table, the buy in of the table is deducted from the user's total money and is stored in a temporary table, in which the user can bet with
 - b. The money in the table is updated during play
 - c. Once a player leaves a table their money from the table is added to the player's total money and the database is updated
3. User passwords are stored with the SHA-256 hash
4. Players will be able to create table, and the and join them through the home page where all current tables are displayed
5. If a table has not been used in 15 minutes, it is deleted
6. The pack in each table is shuffled between rounds
7. The dealer button moves to the dealers left each round
8. Tables have a maximum number of players (between 2 and 8) which can be specified by the table's creator
9. Tables have a buy-in to enter, specified by the table's creator which is used to determine how much a player must put in the table
 - a. Used to calculate the size of the blinds, the small blind is $1/100^{\text{th}}$ the size of the buy in.
10. Once in a table, players can play live poker according to the rules in the Texas hold 'em section in analysis
11. Players will only be able to see their pocket cards and the table's community cards
12. If a player leaves a table, they will automatically fold
13. A leader board shows players ranked by their total money
14. Players can interact with each other using an in-table chat
 - a. The chat can be filtered so that swear words would be censored

15. A how to play page is provided for new players
16. Multiple games on the website can be played at the same time

Extension Objectives

1. Players can create private tables, which require a password to enter
2. Players can add friends and join the table they are in if possible
3. Players can view active friends on the friend's page and join the table through the page
4. Players can add friends by visiting their profile through leaderboard or game
5. Temporary storage of data in poker games could be stored in a NO SQL database as it offers quicker read and write speeds
6. Players can keep track of other stats such as number of hands played, % hands won etc.
7. Players can join multiple tables at once, and switch between them
8. The table could be shown with players in a circle and a pot and community cards in the middle, rather than being text based
9. Cards shown with images instead of text
10. Card and chip animations
11. A re buy in button could be shown once a player runs out of money in a table
12. A poker AI could optionally be added to tables to add players to the game
13. Site uses HTTPS to prevent username and passwords being intercepted, along with poker hands

Design

Overview

I am designing a web-application that allows users to create accounts and play live poker against other players. In each table, there is also a chat allowing players to interact with each other. Users are able to view their ranking on the leaderboard.

I will create a CRUD like interface to begin with (to create and delete tables) and user accounts, so that the web app functions in the way it should before adding the poker aspect to the website. To make the poker game interactive, I will use sockets to achieve two-way communication, however logic must be run on the backend server and send values to the frontend service as any script or logic running on the client device could be easily manipulated by malicious users.

The Django Framework

Fundamentals of Django

The Django Framework is designed to encapsulate each aspect of the project in its own 'app'.

Django is fundamentally made up of 4 different types of files:

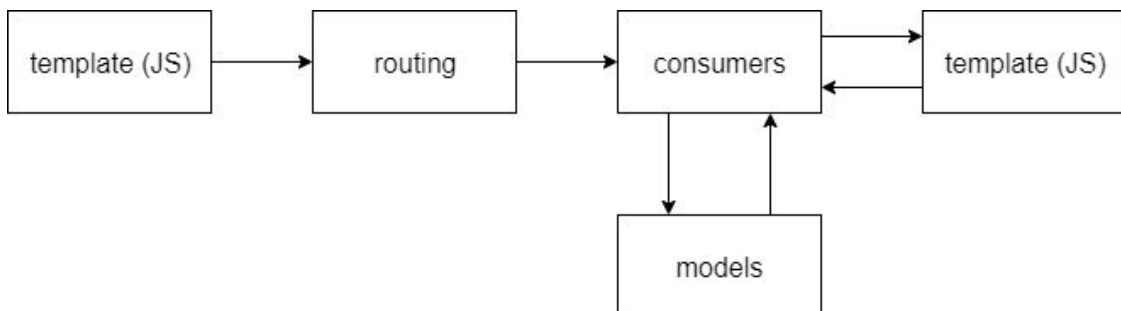

- `models.py` – Defines your data model and contains the fields and behaviours of the data you are storing. Each model maps to a database table and each attribute to a field. A model is defined in a class and as such this allows Django to interact with DB records like objects. This is extremely useful in creating queries and editing records as it does not require a manual SQL query. The model can include methods to manipulate the DB data.
- `forms.py` – Django can create forms that you can interact with like objects in a very similar form to the way it handles models. You can use a model to map out and save a form. For example, to create a poker table, the form can use fields from the table model instead of writing out the fields again. As the form is modelled directly off the table model, it can be validated and saved directly into the database.
- `urls.py` – Uses regex to capture URL patterns to retrieve a view. It can parse arguments in the URL to pass to the view e.g. a URL regex `'tables/<int:pk>'` can be mapped to a view that takes `pk` as a parameter to fetch data from a specific table.
- `views.py` – Called by `urls.py`. Takes the web request and returns a web response. When rendering a web page, it can pass context (a dictionary of variables) to the template. The view function can do anything a standard python function can do, as long as it returns a web response.
- `template` – an HTML file with special syntax describing how dynamic content can be inserted into the HTML.

Django Channels

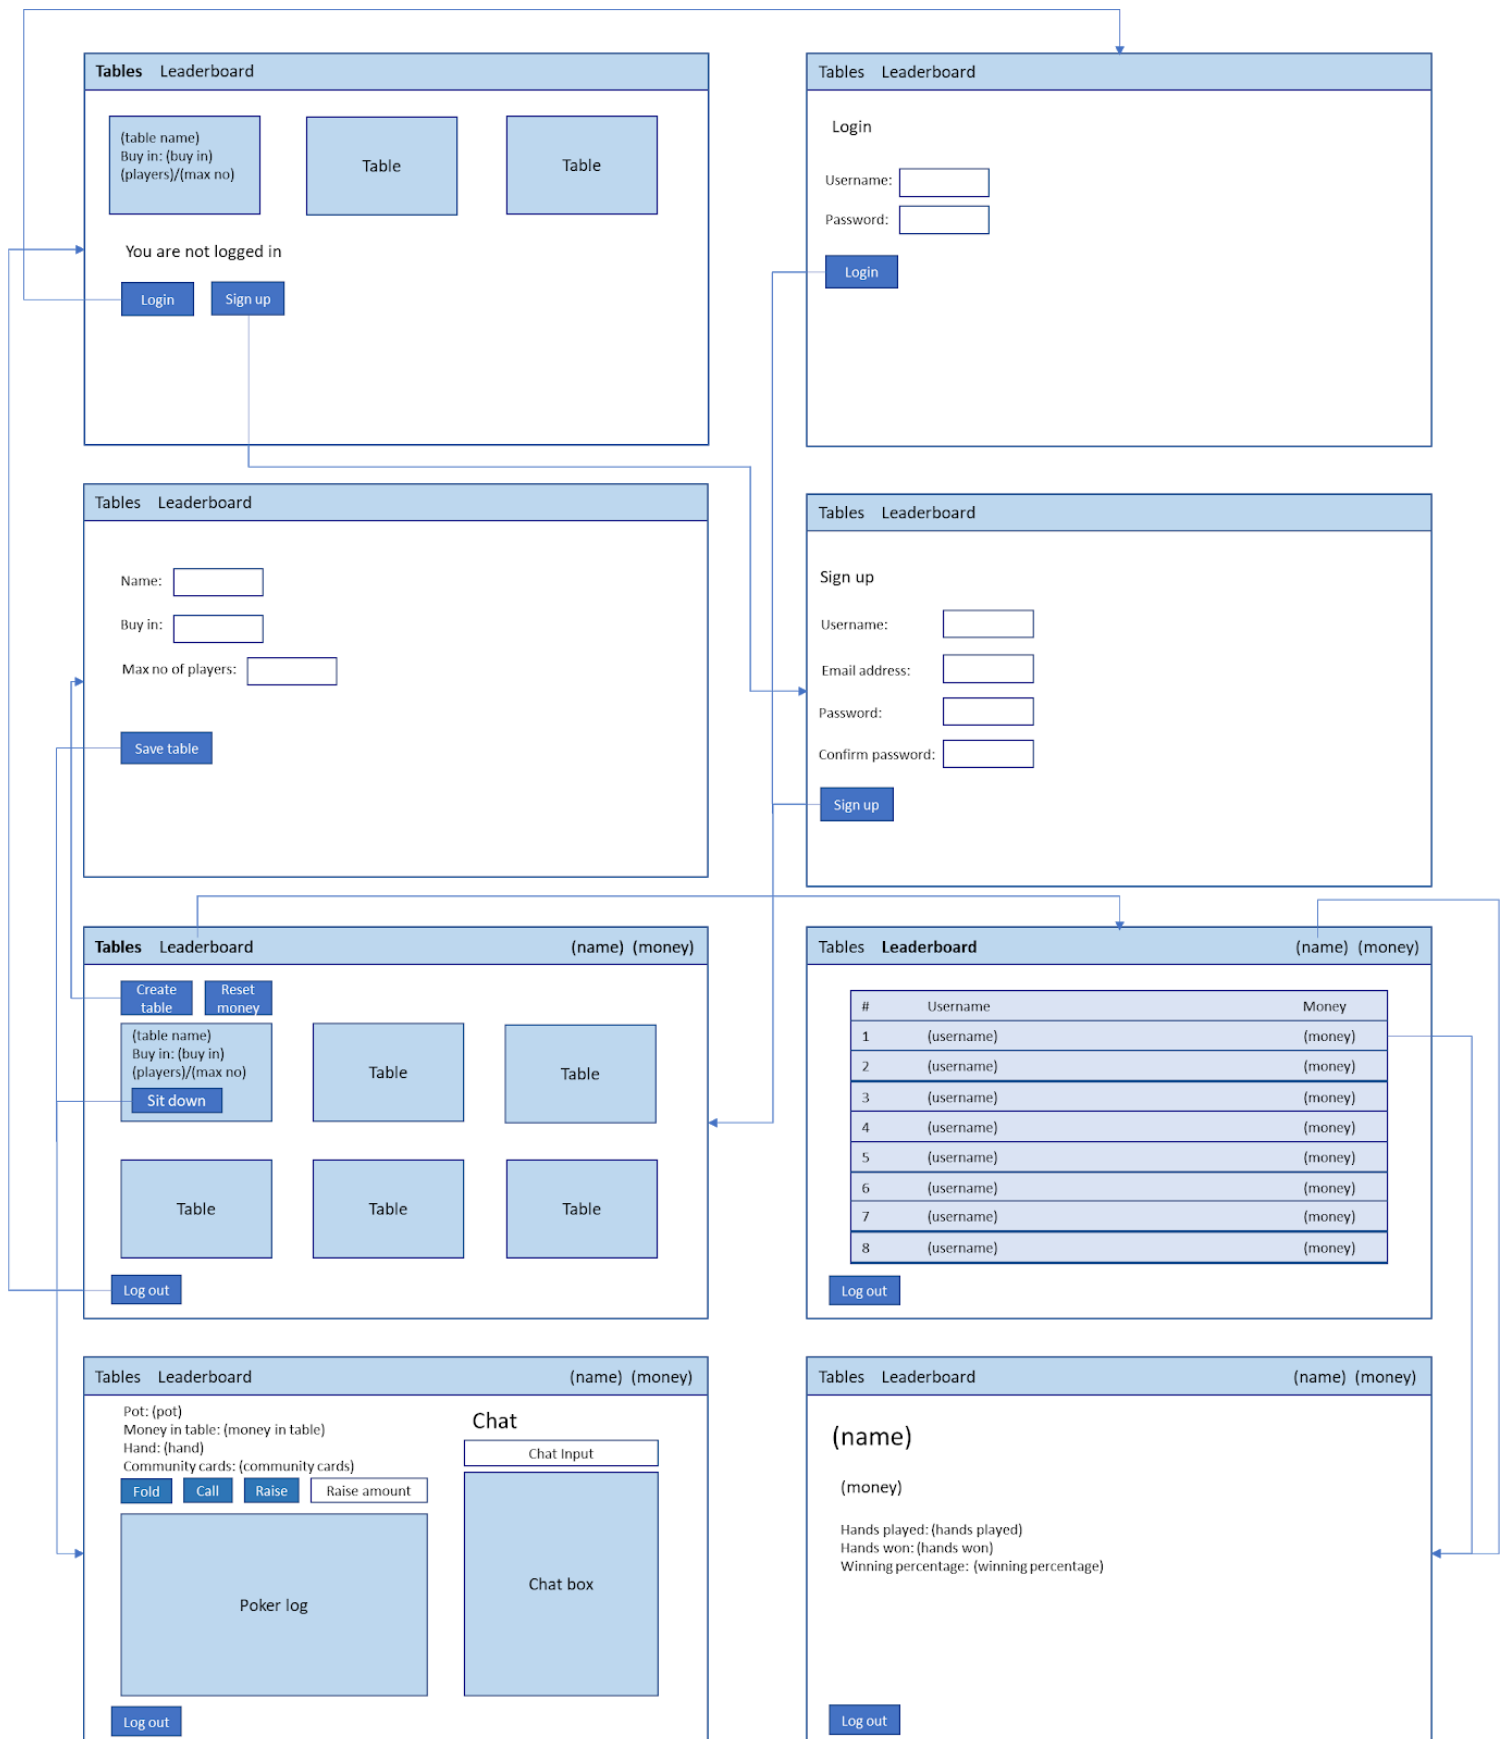

A synchronous socket library for Django. Its base features work very similarly to Django:

- The templates' JavaScript creates a web socket.
- `routing.py` – uses regex to capture the web socket retrieves a consumer (just like `urls.py`).
- `consumer.py` – A class similar to views. It can interact with the models and create web socket groups to send data to multiple users. The consumer has specific methods to process users connecting and disconnecting from the sockets, as well as sending and receiving data to and from JavaScript.

User Interface Design

Website wireframe

Key

- Light blue box – object
- Dark blue box – button
- White box – input
- () – variables
- The leader board table are CSS buttons that link to each user's profile

This is a wireframe of the web-app. The table page acts as a home page where users can view, create and join tables. A public leaderboard displays every user by their money, and users can view other players profiles by clicking on them through the leaderboard.

Users can also view their profile by clicking on their username in the nav bar. The fold, call and raise buttons can be hidden if it is not the user's turn or if they cannot perform the action at that stage.

Users must be logged in and have sufficient money to join the table.

The Poker Algorithm

Joining the game

Game view

When the user sits down at a table, the program verifies whether they have sufficient money to play at the table, and that the table is not full. If verified, the user joins the game otherwise they are redirected back to the index page.

login required to access

Function game

```
table <- get Table object
if users money >= tables buy in and players in table < max players in table
  start daemon thread on poker main function
  return render of game.html
return a redirect to the index view
```

Adding player to table

When the poker algorithm runs, it determines whether they are the only player at the table, in which case a new poker instance is instantiated. Otherwise it adds the player to the table and returns.

Function main

```
get Room object for Table
add player to Room

if Room does not exist
  create Room object
  add player to Room
  startGame()
```

Finding hand strengths

Finding cards of the same rank

hand <- players cards sorted in descending order with Aces counting high and low
finalHand <- []

```
Function checkRank(hand)
  sameRank <- []
  i <- 0
  while i < 6
    temp <- hand[i]
    while hand[i] has same rank as hand[i+1]
      temp += hand[i+1]
      i += 1
    if length of temp > 1
      sameRank += temp
  sort sameRank by length of arrays
  sameRank <- first two arrays of sameRank
  if sameRank[0] has length of 4
    sameRank <- sameRank[0]
    hand is 4 of a kind

  elif length of sameRank = 2
    if length of sameRank[0] = 3
      hand full house
    else
      hand is two pair

  else
    if length of sameRank[0] = 3
      hand is 3 of a kind
    else
      hand is pair

  put all cards in sameRank in 1D array
  add all other loose cards to sameRank
  finalHand <- first 5 cards in sameRank
```

Finding flushes

```
Function flush(hand)
  for each suit
    flush <- []
    for each card in hand
      if card is same suit as the suit that's being compared
        flush += card
    if length of flush is 5 and flush is the highest strength found
      hand is flush
      finalHand <- flush
```

Finding straights

If cards are the same in a hand, the function is recursively called to check for opportunities for straight flushes.

```
Function straight(hand)
  straightHand <- []
  for each card in hand
    if card is one more than next card
      add the cards to straightHand
    else if the card is the same as the next card
```

```

        straight(hand without the card)
    else
        straightHand <- []
        if there are 5 cards in straightHand
            if cards are of same suit
                finalHand <- straightHand
                if straightHand begins with high Ace
                    hand is royal flush
            else
                hand is straight flush
        else
            if straight is the highest strength found
                hand is straight
                finalHand <- straightHand

```

Creating winner order queue

The algorithm finds which players win over others by creating a queue of players in winning order. If two (or more) players have the exact same strength, they share the pot, and are added to playerWin in a single array.

Sorting the players

Sort the players by hand strength and add players of same strength to repeated array for further processing

```

win <- [players sorted by hand strength]
Function clash
    repeated <- []
    binary sort win
        if win items are equal
            repeated += both items

```

Grouping players of same strength in arrays

Many players may have the same strength hand and the players are added in pairs, so if a player is the same as a player in the previous iteration then all 3 players in the current and previous iteration have the same strength hand. So, the other player in the current iteration is appended to the previous iterations array.

```

split <- []
Function splitWork(repeated)
    for player in repeated, step of 2
        if player in previous split array
            split[last item in array] += next player in repeated
        else:
            split += [player, next player]

```

Adding players to playerWin queue

Players are added to playerWin array in strength order, and if they appear in a split array, they share hand strength with other players so the split array is added instead. Single players are still added in their own arrays to keep the array depth consistent. As two or more players are in each split array the array will be added for each player. Therefore, any duplicate arrays after the first one in the queue are removed.

```

playerWin <- []
Function WinQueue

```

```

for player in win
  if player in a split array
    playerWin += split array the player is in
  else
    playerWin += [player]
remove duplicate arrays in playerWin

```

Dividing the pot

Determining the winners

For some all-in scenarios some players in the game have not put the same amount of money as other players, so the algorithm iterates through the playerWin queue until the entire pot is given out.

```

Function winner
  a <- 0
  playerWin <- list of players sorted by hand strength
  while pot != 0
    winners <- []
    for player in playerWin[a]
      if player has not folded
        winners += player
    pot = distributeMoney(players, winners, pot)
    a+=1

```

Distributing money

A recursive function evenly distributes to the winners the minimum amount of money a player in the list has put in multiplied by the number of players to put that amount of money in.

```

players <- players in table
Function distributeMoney(players, winners, pot)
  if there are still winners left
    money <- least amount of money a player in players has put in * no players
    moneyWon <- money / no of winners
    if money cannot be evenly distributed between winners
      newWinners <- winners without the winner who bet last
      pot += distributeMoney(players, newWinners, odd money in pot)

    increment each winner by moneyWon
    pot <- pot - money
    players <- players without the player who put the least money in
    winners <- removed corresponding winner if needed
    distributeMoney(players, winners, pot)
  return pot

```

Making the winner message

The hands of the players are shown in a clockwise manner from the dealer. If the player's hand strength is the same as or beats every other hand currently shown, their hand is shown to all players.

```

Function makeWinnerMessage
  message += ''
  showHands <- []

```

```

winningIndex <- 999
player <- player to dealers left
while not iterated through every player or in first loop
  get index of player in playerWin
  moneyWon <- money player won in round
  if index <= winningIndex and player hasn't folded
    showHands += [player, player's cards, hand strength, moneyWon]
for player in showHands
  message += data from player

```

Database Design

The database stores each user's information and their encrypted password in the table **CustomUser**. It also stores the table information in **Table**. Once the poker algorithm is run, it creates a **Room** object that carries information about the current game. This has a one to one relationship with the **Table**.

Room persists as long as there are players in the table. Every time a player joins the game, they make a **Players** object that persists until they leave the table. This has a one to one relationship with **CustomUser** and a many to one relationship with the **Room**.

The **Players** object stores the money in play on the table and whether it is the players turn. This is so the poker algorithm can communicate with the consumer program, that only accepts player actions if it is the players turn.

The **Players** and **Room** tables could be replaced with a temporary storage NoSQL database using MongoDB for better read and write performance as the data changes frequently.

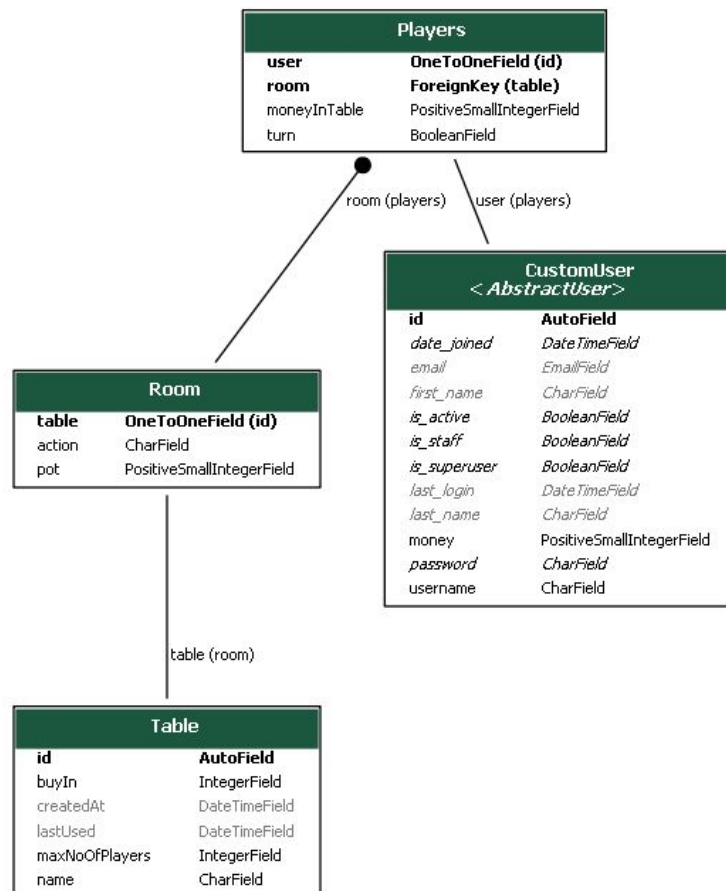

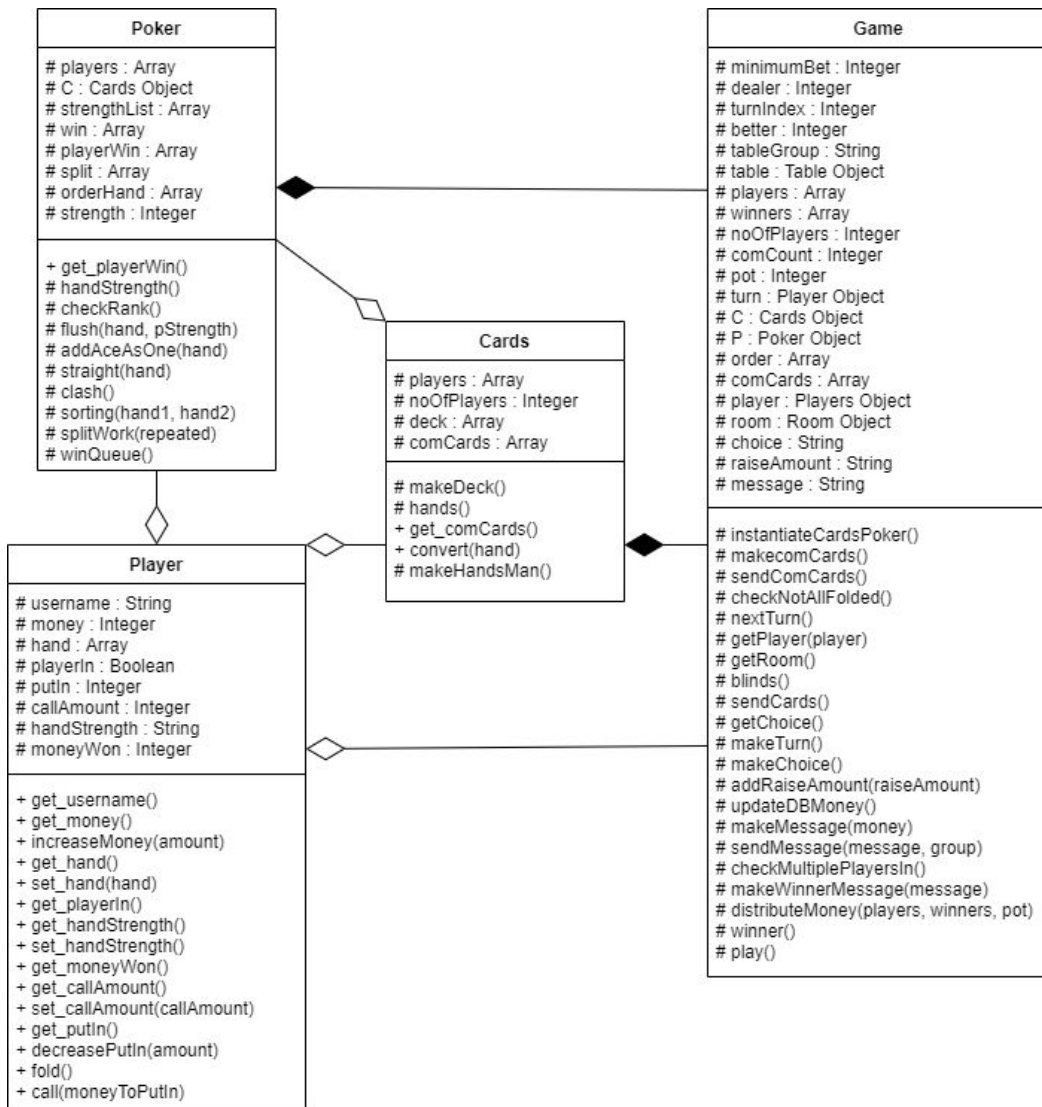

Table Design

The online poker tables on the web app will be designed so that any user can create a poker table, specifying the buy in and the maximum number of players. The minimum bet is 1/100th of the buy in. If a table is empty for over 15 minutes it will be deleted. The buy in must be from 100 – 100000000 credits and the maximum number of players must be from 2-8.

User Design

Each user will be able to create and join any table if they have enough money to meet the buy in. The starting amount of money for a user will be 1000 credits, which can be reset if they go below that. Users will be able to gain credits by winning them off other people in poker tables, and the credits will persist even after they log out. The users can view their rank against others on the leaderboard.

OOP Design

Implementation

2D Array

self.win is a 2D array that holds the players cards and hand strength in order to find the winning hands.

```
self.win.append([self.strength, player, self.orderHand[:]])
```

Anonymous function

```
sortedPlayers = sorted(players, key = lambda x: x.putIn)
```

Strength of hand

Finding cards of the same rank

The algorithm iterates through every card in the hand, adding arrays of cards of the same rank to the sameRank array. It then sorts the array by the length of the arrays inside of it as 3 cards of the same rank will always be better than two and so on. The array is then truncated to only include the first two items in the array or less as a hand can only be made up of 5 cards so 3 pairs for example are never necessary. The hand strength is then calculated by checking the length of the sameRank array and the length of the first item in the array. The sameRank array is then converted into a 1D array and any cards not in sameRank appended in order onto the end. The sameRank array is then truncated to only include 5 cards and written to orderHand.

```
def checkRank(self, hand):
    #determines whether cards are a pair or 3 of a kind,
    #alternatively a two pair or fullhouse
    def twoThree(pStrength2, pStrength3):
        if len(sameRank[0]) == 3:
            return pStrength3
        else:
            return pStrength2

    i = 0
    sameRank = []
    while i < 6:
        temp = [hand[i]]
        try:
            #adds cards of same rank to temp
            while hand[i][0] == hand[i+1][0]:
                temp.append(hand[i+1])
                i+=1
            else:
                i+=1
        except IndexError:
            pass
        #if more than one card of same rank add to sameRank
        if len(temp) > 1:
            sameRank.append(temp[:])

    #sort by length of same ranked cards,
    #e.g. 4 of a kind > 3 of a kind > pair
    sameRank.sort(key = lambda x: len(x), reverse=True)
```

```

sameRank = sameRank[:2]
if len(sameRank) != 0:
    #four of a kind
    if len(sameRank[0]) == 4:
        sameRank = sameRank[0]
        self.strength = 7

    #two pair or full house
    elif len(sameRank) == 2:
        self.strength = twoThree(2, 6)

    #pair or three of a kind
    else:
        self.strength = twoThree(1, 3)

#put all cards from sameRank in 1D array
temp = []
for cards in sameRank:
    for card in cards:
        temp.append(card)

#add cards not included in sameRank
for card in hand:
    if card not in temp:
        temp.append(card)
#make orderHand
self.orderHand = temp[:5]

```

Finding flushes

```

def flush(self, hand, pStrength):
    #iterates over all 4 suits
    for i in range(4):
        flush = []
        for card in hand:
            #appends card to flush array if same suit
            if card[1] == i:
                flush.append(card)

        if len(flush) == 5 and self.strength < pStrength:
            self.strength = pStrength
            self.orderHand = flush[:5]

```

Finding straights

The algorithm first temporarily adds an ace, usually represented as 14, as a 1 to the hand as aces can be used as low or high in straights. The algorithm then iterates through this new hand to check if any 5 cards are in sequential order. As the cards are sorted from high to low the algorithm will find and use the highest straights first. If two cards are of the same rank, the method recursively calls itself excluding one of the same ranked cards each time. This is because one of the cards may be part of a straight flush while the other may only lead to a straight. Once the algorithm has found a straight hand, it then calls the flush method to check whether the hand is a flush or not.

```

def addAceAsOne(self, hand):
    #temporarily adds ace as 1
    for card in hand:

```

```

        if 14 in card:
            if [1, card[1]] not in hand:

    if self.strength == 8 and self.orderHand[0][0] == 14:
        self.strength = 9

```

Binary Sort

If two players have the same hand strength, the program needs to sort the cards by the 'strength' of the card e.g. Ace > King. The cards are already ordered so the cards that make hand strength are at the front of the hand, e.g. the 10 pair comes before the Ace.

A binary sort is used to sort the hands as there will be at most 8 players in the table so the overhead necessary for a merge sort would not be efficient. If two players have exactly the same strength then the two players are appended to the split array in an array.

```

#binary sort but adds the players to repeated array if values are the same
def clash(self):
    repeated = []
    flip = True
    while flip:
        flip = False
        for a in range(len(self.win)):
            if len(self.win) > a+1:
                if self.win[a][0] == self.win[a+1][0]:
                    flip = self.sorting(self.win[a][2], self.win[a+1][2])

```

```

        if flip == 'split':
            flip = False
            repeated.append(self.win[a][1])
            repeated.append(self.win[a+1][1])

        elif flip:
            temp = self.win[a]
            self.win[a] = self.win[a+1][:]
            self.win[a+1] = temp[:]

    self.splitWork(repeated)

def sorting(self, hand1, hand2):
    a = 0
    #finds the first card where the values differ
    while hand1[a][0] == hand2[a][0] and a < 4:
        a+=1

    if hand1[a][0] > hand2[a][0]:
        return False

    elif hand1[a][0] < hand2[a][0]:
        return True

    else:
        return 'split'

#adds players with the the same hand to split in an array
def splitWork(self, repeated):
    for a in range(0, len(repeated), 2):
        if a - 1 >= 0:
            #the players are added in pairs, so if a player is the same as
            #a player in the previous iteration then all 3 players in the
            #current and previous iteration have the same strength hand.
            #So the other player in the current iteration is appended to the
            #previous iteration array
            if repeated[a] == repeated[a-1]:
                #-1 is the index of the last item in the array
                self.split[-1].append(repeated[a+1])
            else:
                self.split.append([repeated[a], repeated[a+1]])
        else:
            self.split.append([repeated[a], repeated[a+1]])

```

List operations

```

def makeDeck(self):
    self.__deck = [[k, j] for j in range(4) for k in range(2,15)]

```

Queue

Creating

From the sorted array created by the binary sort, the player object from each hand is appended to the playerWin queue in an array. If the player object is in the split array, i.e. the player has the same strength as another player and so would share the pot if won, the split array is appended to the win queue.

This is why the player object is appended in an array in first part so all the player objects are 2 layers deep. Also includes list operations append and remove.

As there is more than one player in the split array, the array will be appended more than once to playerWin. The bottom 3 lines remove any duplicate arrays in playerWin by converting the player arrays to tuples and creating a dictionary using the newly made tuples as keys. As dictionary keys must be unique, any tuples that are already a key are ignored. The dictionary and tuples are then converted back into arrays.

```
#adds each player to playerWin in an array
def winQueue(self):
    for strength, player, hand in self.win:
        added = False
        for players in self.split:
            if player in players:
                #if players in split it adds the split array instead
                self.playerWin.append(players)
                added = True
        if not added:
            self.playerWin.append([player])

    #remove duplicate split arrays
    self.playerWin = [tuple(x) for x in self.playerWin]
    self.playerWin = list(dict.fromkeys(self.playerWin))
    self.playerWin = [list(x) for x in self.playerWin]
```

Using

To distribute the money according to how much money each player has put in the pot, the program de-queues the first array in the playerWin queue and passes all the players in the array that haven't folded to the distributeMoney method.

```
def winner(self):
    a = 0
    while self.pot != 0:
        for player in self.P.playerWin[a]:
            if player.playerIn:
                self.winners.append(player)
        print('winners', self.winners)
        self.pot = self.distributeMoney(self.players[:,], self.winners[:,], self.pot)
        print(self.pot)
        self.updateDBMoney()
        a+=1
    self.makeWinnerMessage()
    self.sendMessage(self.message, self.tableGroup)
```

Recursive Function

The recursive function sorts the players by the amount of money each player has put in. It calculates the amount of money each winner is due based on the number of winners and players in the array and decreases the amount each player has put in.

With each iteration it calls the function with one less player and deletes winners that have been de-queued from the players array. In certain situations, the total pot cannot be divided equally by the number of players.

The extra chips must be shared out as equally as possible, so the program divides the money by all the winners except the one furthest to the dealers right.

```
def distributeMoney(self, players, winners, pot):
    sortedPlayers = sorted(players, key = lambda x: x.putIn)
    winners.sort(key = lambda x: x.putIn)
    if len(winners) != 0:
        money = sortedPlayers[0].putIn

        #money given out equal to the minimum players putIn
        #or pot if in the oddMoney recursion
        moneyMade = money * len(sortedPlayers)
        if moneyMade > pot:
            moneyMade = pot
            money = pot // len(sortedPlayers)

        #if the money cannot be shared equally
        oddMoney = moneyMade % len(winners)
        if oddMoney != 0:
            print('odd money in pot:', str(oddMoney))
            #share the money between the all the winners except the last
            a = -1
            while players[a] not in winners:
                a-=1
            print('removing winner:', players[a].username)
            tempWin = winners[:]
            tempWin.remove(players[a])
            pot += self.distributeMoney(players[:], tempWin, oddMoney)

        #decrease each players putIn by the min players putIn
        #increase each winners by the (min players putIn * players)// no winners
        moneyWon = moneyMade // len(winners)
        for player in sortedPlayers:
            player.decreasePutIn(money)
            if player in winners:
                player.increaseMoney(moneyWon)

        #decrease pot by money given out
        pot -= moneyMade
        #delete minimum putIn player
        players.remove(sortedPlayers[0])
        if winners[0] == sortedPlayers[0]:
            del winners[0]

        pot = self.distributeMoney(players, winners, pot)
    return pot
```

Create showdown winner message

Iterates through players from dealers left, and if their hand can beat or match any hand shown, they show their cards.

```
def makeWinnerMessage(self):
    self.message = '\n-----'
    showHands = []
```

```

startIndex = currentIndex = (self.dealer+1)%self.noOfPlayers
winningIndex = 999
firstRun = True
#iterates through each player from dealers left as they show first
while currentIndex != startIndex or firstRun:
    firstRun = False
    for a in range(len(self.P.playerWin)):
        if self.players[currentIndex] in self.P.playerWin[a]:
            currentWin = a

    if self.players[currentIndex].playerIn and currentWin <= winningIndex:
        winningIndex = currentWin
        playerStats = {
            'username': self.players[currentIndex].username,
            'moneyWon': self.players[currentIndex].moneyWon
        }

        if self.checkNotAllFolded():
            playerStats['hand'] = Cards.convert(self.players[currentIndex].hand)
            playerStats['strength'] = ': ' + self.players[currentIndex].handStrength +
            ' '
        else:
            playerStats['hand'] = ''
            playerStats['strength'] = ''

        showHands.append(playerStats)
        currentIndex = (currentIndex+1)%self.noOfPlayers

    for player in showHands:
        winnings = ''
        if player['moneyWon'] != 0:
            winnings = ' won ' + str(player['moneyWon'])
        self.message += '\n' + player['username'] + winnings + player['strength'] + player[
'hand']
        self.message += '\n-----\n'

```

DB Objects

In Django, DB records can be modelled as Python objects. Each DB table is represented as its own class.

Creating DB Objects

Each variable represents a row of the table. The **Table** object can also reference the **Room** object because there's a one-to-one relationship between the **Table** and the **Room**, as instantiated in the **Room** object.

DB classes can also contain methods that can be run on the data in the table. These can be run by calling the method from a **Table** object as with normal OOP. For example, the **Room** table contains the players in a table. However, the **Room** object only exists while players are in the table. So, if the table has no players in it, trying to get the number of players in the table will return an error.

```

class Table(models.Model):
    def getNoOfPlayers(self):
        try:

```

```

        players = Players.objects.filter(room=self.room)
        for player in players:
            if player.moneyInTable == 0:
                players.remove(player)
        noOfPlayers = len(players)

    except:
        noOfPlayers = 0
    return noOfPlayers

name = models.CharField(max_length=24, unique=True)
buyIn = models.IntegerField(
    validators=[MinValueValidator(100), MaxValueValidator(100000000)]
)
maxNoOfPlayers = models.IntegerField(
    validators=[MinValueValidator(2), MaxValueValidator(8)]
)
createdAt = models.DateTimeField(auto_now_add=True)
lastUsed = models.DateTimeField(auto_now_add=True)

```

Instantiating DB objects and records, getting DB objects

The function gets the player's user data from the database using the player's username. Getting an object is similar to WHERE in SQL syntax, however must only return one DB object.

It then creates a new DB record using the **CustomUser** object and the **Room** object. This is stored as a one-to-one relationship with **CustomUser** and a foreign key with **Room**.

```

def addPlayer(room, table, username):
    player = CustomUser.objects.get(username=username)
    playerInstance = Players.objects.create(
        user=player, room=room, moneyInTable=table.buyIn
    )
    player.money -= table.buyIn
    player.save()

```

Threading

Creating thread

The view function has an `@login_required` decorator which means that only logged in users can access the function. If the user has the minimum required money to join the table and the table is not full, it starts a daemon poker thread.

A daemon thread runs in the background so the view can return and the program can end to accept more web requests without the daemon thread ending.

```

@login_required
def game(request, pk):
    table = get_object_or_404(Table, pk=pk)
    if request.user.money >= table.buyIn and table.getNoOfPlayers() < table.maxNoOfPlayers:
        pokerThread = threading.Thread(
            target=main, args=(pk, request.user.username), daemon=True
        )

```

```

pokerThread.start()
context = {
    'table': table,
}
return render(request, 'game.html', context)
return redirect('index')

```

Thread function

The function checks for an active **Room**. If a room is found, it adds the player and exits. If the **Room** doesn't exist, it creates a **Room** record and adds a player to the room. It then starts the game.

```

def main(pk, username):
    table = Table.objects.get(pk=pk)
    #check to see if table exists
    try:
        room = Room.objects.get(table=table)
        addPlayer(room, table, username)

    #if room doesn't exist create one
    except Room.DoesNotExist:
        room = Room.objects.create(table=table)
        addPlayer(room, table, username)
        startGame(table)

```

Starting the game

This function runs in an infinite loop starting the next poker round when the previous round finishes.

```

def startGame(table):
    TESTING = False
    playersInGame = []
    dealer = 0
    tableGroup = 'table_' + str(table.pk)
    while True:
        #waits until there is more than one player in the table to start
        table.refresh_from_db()
        while table.getNoOfPlayers() == 1:
            table.refresh_from_db()
            time.sleep(0.2)

        #if single player leaves table before anyone joins
        if table.getNoOfPlayers() == 0:
            print('player left, not in game')
            table.lastUsed = datetime.now(timezone.utc)
            table.save()
            sys.exit()

        #gets players in table
        players = Players.objects.filter(room_id=table.id) #table group is the primary key
        of Room
        makePlayerOrder(playersInGame, players)

        if not TESTING:

```

```

        dealer = (dealer+1)%len(playersInGame)

#starts game
Game((table.buyIn)//100, dealer, tableGroup, table, playersInGame)
time.sleep(0.4)

```

Adding and newly joined players and removing players that have left

```

def makePlayerOrder(playersInGame, players):
    for player in playersInGame:
        #sets all the Player objects back to their base values
        player.newRound()

        #check whether player in playersInGame is in players
        #if not, the player has left
        if not any(x for x in players if x.user.username == player.username):
            playersInGame.remove(player)

    for newPlayer in players:
        #check whether Player object is not already in playersInGame
        #if so, new player has joined the table
        if newPlayer.moneyInTable > 0 and not any(x for x in playersInGame if x.username ==
newPlayer.user.username):
            P = Player(newPlayer.user.username, newPlayer.moneyInTable)
            print(P.username, 'has joined')
            playersInGame.append(P)

    print('playersInGame:', playersInGame)

```

Synchronous web sockets

Server-side

Connecting

This method adds a player to the table group and creates a unique group to receive their cards.

```

class PokerConsumer(WebsocketConsumer):
    #adds the player to the poker group to recieve the community cards and bets
    #adds the player to a unique group to recieve his cards
    def connect(self):
        self.pk = self.scope['url_route']['kwargs']['pk']
        self.player = self.scope['user']
        self.username = self.player.username
        print('player:', self.username)
        self.tableGroup = 'table_' + self.pk
        self.room = Room.objects.get(table_id=self.pk)
        self.censoredList = getCensoredWords()
        #group socket
        async_to_sync(self.channel_layer.group_add)(
            self.tableGroup,
            self.channel_name
        )

        #unique socket

```

```

async_to_sync(self.channel_layer.group_add)(
    str(self.username),
    self.channel_name
)
#accepts all communication with web socket
self.accept()

```

Receiving

If the message is a chat message, sent to group. Else the message must be a poker action, so only accepted if it is the players turn.

```

def receive(self, text_data):
    player = Players.objects.get(user=self.player)
    textDataJson = json.loads(text_data)
    action = textDataJson['action']
    if action == 'message':
        message = textDataJson['message']
        if message != '':
            message = self.username + ': ' + message
            message = censor(message, self.censoredList)

            async_to_sync(self.channel_layer.group_send)(
                self.tableGroup,
                {
                    'type': 'chatMessage',
                    'text': message
                })

    elif player.turn:
        player.turn = False
        textDataJson = json.loads(text_data)
        message = textDataJson['action']

        if message == 'fold':
            action = 'f'

        elif message == 'raise':
            raiseAmount = textDataJson['raiseAmount']
            action = 'r' + raiseAmount

        elif message == 'call':
            action = 'c'

        self.room.action = action
        self.room.save()
        player.save()

```

Sending

Poker method

This method gathers the data for each player to send to the consumer.

```
def sendCards(self):
    for player in self.players:
        if player.playerIn:
            hand = Cards.convert(player.hand)
            async_to_sync(get_channel_layer().group_send)(
                player.username,
                {
                    'type': 'cards',
                    'hand': hand,
                    'comCards': self.comCards,
                    'dealer': self.players[self.dealer].username,
                    'moneyInTable': str(player.money)
                })
    })
```

Consumer method

Method sends the message to the client.

```
def cards(self, event):
    message = 'cards'
    hand = event['hand']
    comCards = event['comCards']
    dealer = event['dealer']
    moneyInTable = event['moneyInTable']
    self.send(text_data=json.dumps({
        'message': message,
        'hand': hand,
        'comCards': comCards,
        'dealer': dealer,
        'moneyInTable': moneyInTable
    })))
```

Disconnecting

Leave socket groups and add money from table to the players total money

```
def disconnect(self, closeCode):
    #disconnects from group sockets
    async_to_sync(self.channel_layer.group_discard)(
        self.tableGroup,
        self.channel_name
    )
    async_to_sync(self.channel_layer.group_discard)(
        str(self.username),
        self.channel_name
    )
    #update player money
    playerInstance = Players.objects.get(user=self.player)
    self.player.money += playerInstance.moneyInTable
    self.player.save()
    playerInstance.delete()

    #if noone left in table delete table
    self.room.refresh_from_db()
    players = Players.objects.filter(room=self.room)
```

```
if len(players) == 0:
    self.room.delete()
```

Client-side JavaScript

Connecting

Connects to socket using a URL, which is captured by routing.py

```
var pokerSocket = new WebSocket(
  'ws://' + window.location.host +
  '/ws/tables/' + pk + '/');
```

Receiving

Part of the receiving function. Mainly receiving data and writing it to specific locations on the page.

```
pokerSocket.onmessage = function(e) {
  var data = JSON.parse(e.data);
  var message = data['message'];
  if (message === 'It\'s your turn') {
    var putIn = data['putIn'];
    showButton('buttons')
    if (putIn > 0) {
      document.getElementById('call').value = ('Call ' + putIn.toString(10));
      showButton('fold')
    }
  } else {
    document.getElementById('call').value = ('Check')
    hideButton('fold')
  }
  document.querySelector('#poker-log').value = (message + '\n') +
  document.querySelector('#poker-log').value;

  } else if (message !== 'message') {
    hideButton('buttons')
  }

  if (message == 'cards') {
    var hand = data['hand'];
    var comCards = data['comCards'];
    var dealer = data['dealer'];
    var moneyInTable = data['moneyInTable'];
    document.getElementById('hand').innerHTML = ('Hand: ' + hand);
    document.getElementById('com-cards').innerHTML = ('Community cards: ' + comCards);
    document.getElementById('money-in-table').innerHTML = ('Money: ' + moneyInTable);
    document.getElementById('dealer').innerHTML = ('Dealer: ' + dealer)

  } else if (message == 'winner') {
    var showdown = data['showdown'];
    var log = data['log'];
    var pokerLog = document.querySelector('#poker-log');
    pokerLog.value = (log + '\n' + showdown + '\n') +
    pokerLog.value;
    document.getElementById('pot').innerHTML = ('Pot: 0');
```

Disconnecting

```
pokerSocket.onclose = function(e) {  
    pokerSocket.send(JSON.stringify({  
        'action': 'fold',  
    }));  
});
```

Regular Expressions and Inheritance, Overriding

The user model inherits from the default **AbstractUser** class that comes by default with Django. The **AbstractUser** class contains user characteristics such as username, password.

The **CustomUser** class uses polymorphism to overwrite the default username field and regex expressions to check that the username is alphanumeric. The username is used for the players unique socket name and must be alphanumeric.

A `__str__` method is called if the object is interpreted as a string e.g. a print statement of **CustomUser** would print the user's username instead of an object instance.

```
class CustomUser(AbstractUser):  
    alphanumeric = RegexValidator(  
        regex=r'^[0-9a-zA-Z_]*$',  
        message='Username must consist only of alphanumeric characters and underscores.'  
    )  
  
    username = models.CharField(max_length=25, validators=[alphanumeric], unique=True)  
    money = models.PositiveSmallIntegerField(default=1000)  
  
    def __str__(self):  
        return self.username
```

Active nav bar tag – regular expressions

To determine whether the user is on a page referenced by the nav bar, the templates calls the tag that searches whether the URL referenced by the button is in the request path (URL). If so, it returns that the button should be active.

```
register = template.Library()  
@register.simple_tag  
def active(request, pattern):  
    stringPattern = '^' + pattern + '$'  
    if re.search(stringPattern, request.path):  
        return 'nav-item active'  
    return 'nav-item'
```

Exception handling and getting and setting private variables

Private variables

```
class Player:
    def __init__(self, username, money):
        self.__username = username
        self.__money = money
        self.__hand = []
        self.__playerIn = True
        self.__callAmount = self.__putIn = 0
        self.__handStrength = ''
        self.__moneyWon = 0
```

Exception handling

A property decorator works so that you can use the property function to get the value like a variable and must return a value. It is equivalent to a getter.

A setter function is called when you attempt to set the property function. It verifies that the input is valid and sets the value or raises an exception if not.

```
@property
def callAmount(self):
    return self.__callAmount

@callAmount.setter
def callAmount(self, callAmount):
    if callAmount >= 0:
        self.__callAmount = callAmount
    else:
        raise Exception('call amount less than 0')
```

Web requests

Server-side scripting

Class Based views

```
class SignUp(generic.CreateView):
    form_class = CustomUserCreationForm #variables must be underscores
    success_url = reverse_lazy('login')
    template_name = 'signup.html'
```

Function based view

```
@login_required
```

```
def game(request, pk):
    table = get_object_or_404(Table, pk=pk)
    if request.user.money >= table.buyIn and table.getNoOfPlayers() < table.maxNoOfPlayers:
        pokerThread = threading.Thread(target=main, args=(pk, request.user.username), daemon=True)
        pokerThread.start()
        context = {
            'table': table,
        }
        return render(request, 'game.html', context)
    return redirect('index')
```

URL paths

HTTP

```
urlpatterns = [
    path('signup/', views.SignUp.as_view(), name='signup'),
    path('p/<str:username>/', views.profile, name='profile'),
]
```

Consumer routing for sockets

```
application = ProtocolTypeRouter({
    #http to views is default
    'websocket': AuthMiddlewareStack(URLRouter([
        path('ws/user/<str:username>/', MoneyConsumer),
        path('ws/tables/<str:pk>/', PokerConsumer),
    ])),
})
```

Handling form POST request and GET request

Form Model

The create table function uses a form created using the **Table** model. The form can then be saved directly as a **Table** record in the DB

```
class TableForm(forms.ModelForm):

    class Meta:
        #specifys what model to use
        model = Table

        #fields from Table model included in form
        fields = ('name', 'buyIn', 'maxNoOfPlayers')

        #read friendly names
        labels = {
            'name': 'Name',
            'buyIn': 'Buy in',
            'maxNoOfPlayers': 'Maximum number of players'
        }
```

Form View

If the form is invalid, the POST request will contain any errors that can be displayed to the user, e.g. password must be more than 8 characters.

```
@login_required
def createTable(request):
    #user submitting the form
    if request.method == 'POST':
        #gets form submission based on the POST request
        form = TableForm(request.POST)
        if form.is_valid():
            #saves form as Table model
            table = form.save()
            return redirect('game', pk=table.pk)

    #user GETting the form
    elif request.method == 'GET':
        form = TableForm()

    context = {'form': form}
    return render(request, 'table-form.html', context)
```

Serializing DB object into JSON using RESTful API

Serializing data

To monitor the number of players in each table and the tables available in real time, I used the Django REST framework to serialize the **Table** model into JSON format. This data is passed to the JavaScript using Django channels as JavaScript cannot interpret Python objects.

The name and maxNoOfPlayers come from the **Table** model and the noOfPlayers field comes from the noOfPlayers MethodField. This runs a method that returns a value. The default method it runs is get_<field name>. In get_noOfPlayers it runs the **Table** object method getNoOfPlayers.

```
class TableSerializer(serializers.ModelSerializer):
    noOfPlayers = serializers.SerializerMethodField()

    class Meta:
        model = Table
        #the fields serailized
        fields = ['name', 'maxNoOfPlayers', 'noOfPlayers']

    def get_noOfPlayers(self, obj):
        #uses the Table method to get the no of players
        return obj.getNoOfPlayers()
```

Creating and using serialized data

This combines the player's money with the money the player has in the table in order to get the total money. The method then serializes the table and sends the serialized data and money to the client using Django channels. This process is repeated until the threading event; stopEvent is set. This is set

on the disconnection of the socket, otherwise the thread would stay alive until the termination of the server.

```
def checkMoney(self, stopEvent):
    while not stopEvent.is_set():
        self.player = CustomUser.objects.get(username=self.username)
        self.totalMoney = self.player.money
        self.moneyInTable = 0
        try:
            self.playerGame = Players.objects.get(pk=self.player)
            self.moneyInTable = self.playerGame.moneyInTable
            self.totalMoney += self.moneyInTable

        except Players.DoesNotExist:
            pass

        self.tables = Table.objects.all()
        self.serializedTables = TableSerializer(self.tables, many=True)
        self.tableJSON = JSONRenderer().render(self.serializedTables.data)

        self.send(text_data=json.dumps({
            'money': self.totalMoney,
            'moneyInTable': self.moneyInTable,
            'tables': json.loads(self.tableJSON),
        }))
        time.sleep(1)
```

Reading from file

```
def getCensoredWords():
    censoredList = []
    path = 'C:\\Users\\Tom\\Desktop\\projects\\web_poker\\censored-words.txt'
    with open(path, 'r') as censoredWords:
        for word in censoredWords:
            w = word.replace('\n', '')
            censoredList.append(w)
    return censoredList
```

Scheduling and custom commands

I created a custom command called startserver that clears any players currently in tables on start-up and runs a thread to delete tables that have not been used for 15 minutes. It then runs the server.

```
class Command(BaseCommand):
    help = 'Calls runserver and cleartables, creates and a daemon thread that removes \
        tables that have been inactive for more than 15 minutes'

    def add_arguments(self, parser):
        parser.add_argument(
            'addrport', nargs='?', type=str, default='127.0.0.1:8000', help='ipaddr:port'
        )

    def handle(self, *args, **kwargs):
```

```

    #os.system('docker run --name channels_app -p 6379:6379 -d redis:2.8')
    call_command('cleartables')
    addrport = kwargs['addrport']
    thread = threading.Thread(target=self.removeTables, daemon=True)
    thread.start()
    call_command('runserver', '--noreload', addrport)

def removeTables(self):
    while True:
        tables = Table.objects.all()
        for table in tables:
            timeDiff = datetime.now(timezone.utc) - table.lastUsed
            timeDiff = timeDiff.total_seconds()/60
            if timeDiff > 15 and table.getNoOfPlayers() == 0:
                print('deleting %s, not used for: %d minutes' % (table.name, timeDiff))
                table.delete()
        time.sleep(10)

```

Complex SQL – leaderboard view

```

def leaderboard(request):
    users = CustomUser.objects.filter().values('username', 'money').order_by('-money')
    context = {
        'users': users
    }

    return render(request, 'leaderboard.html', context)

```

Testing

Test videos

Test video

bit.ly/project-full-tests

Normal use

bit.ly/project-normal-use

Test table

Hands are ordered by card rank

Player 1: dealer

Player 2: SB

Player 3: BB

Test no	Test description	Expected outcome	Actual outcome	Video timestamp
1	User signs up and logs in	If the data given by the user complies with profile restraints, the users profile is stored in the database. The user can then log in with username and password.	As expected	00:14
2	Passwords stored with the strong hash SHA-256	The password 'testing11' will be stored in the database as:	As expected	01:14
3	Logged in user clicks their username in the top right of the dashboard	The website recognises the user is accessing their own profile and shows your profile on the profile page	As expected	01:20
4	A logged in user creates a table called table1 with buy-in 100 and max no of players 3	A table is created and stored in the database. The user will be redirected to the table	As expected	01:55
5	A player joins a table while another user is viewing the home page	The number of players in the table is incremented by 1 on the user's home page without refreshing the page	As expected	02:28
6	Player 1 sends message 'hello' in chat	Every player in the table receive a message in the chat log: 'Player 1: hello'	As expected	02:31
7	Player has cards: K♣ K♦ 10♦ 8♦ 4♥ 4♦ 4♠	Detects a full house hand, uses cards: 4♥ 4♦ 4♠ K♣ K♦	As expected	03:21

8	Player has cards: 8♥7♥6♥5♥4♥3♥2♥	Detects a straight flush hand, uses cards: 8♥7♥6♥5♥4♥	As expected	04:15
9	Player 1 hand: 2♥2♦2♠A♦K♦ Player 2 hand: A♥A♦K♠K♦Q♠	Player 1 beats player 2 as three of a kind is of greater strength than two pairs	As expected	05:03
10	Player 1 hand: 7♥7♦K♠J♠6♠ Player 2 hand: 7♥7♦K♠10♦6♠	Player 1 beats player 2, as the Jack kicker is higher rank than the 10	As expected	05:59
11	Player 1 hand: 7♥7♦K♠J♠6♠ Player 2: K♠J♠6♠5♠2♠ Player 3: 7♥7♦K♠10♦6♠	Player 1's cards are shown as he is first to the left of the dealer, player 2 cards are hidden as he has folded, even though he has the strongest hand. Player 3 cards are shown even though he cannot beat player 1's hand because the hands are shown from the dealers left and as player 1 is the dealer his hand is shown last.	As expected	06:30
12	Player 1 and 2 calls BB, player 3 raises the bet by 10, player 1 goes all-in, player 2 folds, player 3 calls the all-in	The betting round continues back round to the player 3 as he was the last to bet in the round. The game is then skipped to showdown as only player 2 is capable of betting.	As expected	06:30
13	Player 1 hand: 7♥7♦K♠J♠6♠ Player 2 hand: 7♠7♦K♠J♠6♠ Player 3 hand: K♠J♠7♦6♠4♠ Player 1 raises 1 and player 2 and 3 call the bet. All players check till the round is finished.	Player 1 and player 2 have the same hand, so the pot is split between them, showing them both as winners in the poker log. However, the pot cannot be fairly split between the two players so the odd money is allocated to player 1 as the dealer is first in the betting order.	As expected	07:23
14	Player 1 hand: 7♥7♦7♠K♠J♠ Player 2 hand: K♠K♠J♠7♦6♠ Player 3 hand: K♠J♠7♦6♠5♠ Player 1 goes all-in with 50, player 2 re-raises 50 and 3 call the bet.	A side pot is created as player 1 cannot stand to win all the money in the pot. Player 1 has the strongest hand so wins the side pot of 150, the remaining 100 goes to player 2 with the second strongest hand.	As expected	07:50

15	Player leaves the table	Hand is automatically folded	As expected	08:21
16	User tries to enter a full poker table then tries to enter a table with not enough money to meet the buy-in and finally a not logged in users try to join a table	Users are redirected to the home page	As expected	09:08
17	User accesses leaderboard page, clicks on themselves and other users from the leaderboard.	A table of all players on the website shown, ordered by their total money. The rows of the table are buttons that redirect the user to the requested user's profile. The website recognises a user accessing their own profile and displays the message your profile when clicked on.	As expected	10:20

Possible tests

Poker algorithm

- The deck is randomly shuffled each game
- 2 random unique cards are dealt to each player and 5 more dealt as community cards
- Hands consist of the strongest set of 5 of the above 7 cards
- The algorithm detects hands:
 - o High card
 - o Pair
 - o Two Pairs
 - o Three of a kind
 - o Straight
 - o Flush
 - o Full house
 - o Straight flush
 - o Royal flush
- The card rank is used to judge cards of same strength e.g. Ace beats a King
- Flush and straight use highest ranking cards first
- The full house 3 of a kind takes precedence in comparing hand rank
- Kickers (cards not used to contribute to the hand strength) used to break ties in strength
- Stronger hands beat weaker hands e.g. three of a kind beats a pair
- The dealer button moves clockwise each round
- Betting turns move clockwise around the table from the dealer
- If a player bets betting continues to that player, i.e. the round continues until every player has either matched the largest bet, gone all-in or folded
- If a player goes all-in, they will not be asked to bet again

- If players are all-in and can no longer bet the community cards are shown and the game goes to showdown
- The algorithm detects if people have same ranking hand and shares pot between them
- Shared pots are calculated based on how much money each player put in
- A player's hand not shown if folded
- Player hands are shown from dealer left
- A hand is only shown if it can beat the current best shown hand
- In situations where the pot cannot be shared fairly, the odd chips go to the players that is first in the betting order
- Every round the SB and BB are compulsory posted by the two players to the dealers left
- The SB and BB rotate with dealer each game
- If a player leaves the table, they automatically fold their current hand
- When a player leaves their money in the table is added to their total money
- The amount of money in a game stays consistent i.e. no lost chips
- Any players still in a game can either raise call or fold on their turn
- If the current bet is 0 the call button replaced with check and the fold button is removed
- Players cannot make an action (call, raise fold) if it is not their turn
- Player action buttons disappear if not their turn
- Invalid raise values, i.e. not a positive integer, are caught and the user is prompted to enter the value again
- Pot, players hand, current money in table, dealer, community cards shown to player at the top left of the page
- Total player money (money in table + money outside table) updated live on top right

Poker log

- The round winners, necessary players cards and hand strength along with money won by each player is shown at the end of the round
- Once a player chooses an action it is printed in the chat
- Community cards printed once turned
- SB BB players shown
- 'It's your turn' message to indicate to the user it is their turn

Poker chat

- Players can send and receive messages in chat
- When a player sends a message, it has <username>: prepended to message
- Words in censor list file censored out of the message with an appropriate amount of *
- Players cannot enter messages greater than 100 characters

Website interface

- Players on leaderboard page shown in a descending order by their total money
- Tables that have not been used for more than 15 minutes are removed
- All records in the temporary storage DB tables Players and Room are removed when the server is first started
- The current page in the navigation bar is highlighted

- If the user scrolls over navigation bar button the text is highlighted

Any user

- Can view every player on leaderboard page
- Users can click on player on the leaderboard to view their profile
- Can see the current tables
- Can view the number of players in a table be updated live
- Can read the how to play page
- Can sign up and log in
- Sign up users must comply with user restraints:
 - Username:
 - Can have a maximum length of 25
 - Can only use alphanumeric characters and underscores
 - Password:
 - Can't be too similar to other personal information.
 - Must contain at least 8 characters.
 - Can't be a commonly used password.
 - Can't be entirely numeric.
- CSRF tokens used in sign up and log in process to prevent CSRF attacks
- All new users start with 1000 money
- Users' passwords stored using strong hashing algorithm with salt

Logged in users

- Users can join tables in which they have enough money to meet the initial buy-in and are not full, if not they are redirected to the home page
- Can create tables
- Cannot create tables with buy in under 100, max players 2-8. If the form data does not meet the requirements then an error is shown on how to fix it and the user can submit the form again
- Users can click their username on the top right to reach their profile
- Website recognises a user accessing their own profile
- Users can reset their money to 1000 if less than that amount from the home page
- Users over 1000 cannot reset their money
- Users can log out
- Users cookies saved in browser so can be automatically logged in after the tab is closed

Evaluation

Analysis of objectives

1. **Players will be able to register with a username and password, and log in/out. The users account information is then stored in the database**

The home page of the website has log in and sign up buttons for users not logged in. The buttons lead to web forms in which the users can enter their account information. If the data is not valid (e.g. not valid email format) or incorrect (wrong username password combination) the forms provide feedback and the user can enter it again. Once a user is logged in a log out button is given at the bottom of every page. The users account information is stored in the **CustomUser** table in the SQLite3 database. This objective has been fully met.

2. **A player's total money is stored in a database.**

A player's money is stored in their **CustomUser** record in the database.

- a. **On entering a table, the buy in of the table is deducted from the user's total money and is stored in a temporary table, in which the user can bet with**

On joining the table, the addPlayer function reduces the players money by the table buy in. The players current money in table is stored in the python Player object in the poker algorithm and in the temporary **Players** table.

- b. **The money in the table is updated during play**

The money in table is stored in the poker algorithm Player object and is synced with **Players** every turn.

- c. **Once a player leaves a table their money from the table is added to the player's total money and the database is updated**

On disconnection from the poker socket in consumers the players total money is incremented by the players money in table.

- d. **Players can reset their money if it reduces below 1000**

If a player's money is below 1000, a button appears on the home page 'Reset money'. Which redirects to reset-money/. This calls the resetMoney view, which checks the user's money is below 1000 and if so sets the users money to 1000. It then redirects back to the home page.

3. **User passwords are stored with the SHA-256 hash**

The user's passwords are stored with the SHA-256 hash in the database, using the PBKDF hashing algorithm

4. Players will be able to create table, and the and join them through the home page where all current tables are displayed

On the home page there is a button for logged in users to create a table which redirects to a web form to create a table. When the user submits a form which is valid, they are redirected to the table. From the home page users can join tables they have enough money to enter. If a user tries to join a table they have insufficient money to enter they are redirected back to the home page.

5. If a table has not been used in 15 minutes, it is deleted

On starting the server, a daemon thread is created that infinitely loops, checking every 10 seconds how long since a table has been last used. If the table hasn't been used for over 15 minutes then it is deleted. The program updates a tables last use on when the last player left, but doesn't delete tables with players still in.

6. The pack in each table is shuffled between rounds

The poker algorithm initializes a new deck array every round, and uses the random library to shuffle the array.

7. The dealer button moves to the dealers left each round

The dealer button is represented by an integer that dictates the position of the dealer in the `playersInGame` array and `players` array in `Game`. It is incremented by 1 each round and taken mod of the number of players.

8. Tables have a maximum number of players (between 2 and 8) which can be specified by the table's creator

The restrictions are made in the **Table** model which the model form that creates the table inherits. The web form has an input to enter the maximum number of players and invalidates the form, prompting the user to enter it again if it is outside that range.

9. Tables have a buy-in to enter (between 100 and 100,000,000), specified by the table's creator which is used to determine how much a player must put in the table

The table buy in is also specified in the **Table** model through the same procedures as above. The table buy is the amount of money that the player plays with in the table.

a. Used to calculate the size of the blinds, the small blind $1/100^{\text{th}}$ the size of the buy in.

The buy in is used to calculate the size of the small blind, $1/100^{\text{th}}$ of the buy in in the poker algorithm. The big blind is conversely twice the small blind so $2/100^{\text{th}}$ of the buy in.

10. Once in a table, players can play live poker according to the rules in the Texas hold 'em section in analysis

Currently, neither I or any end user can find any bugs in the poker algorithm or game. The poker game on my website follows the Texas hold 'em rules specified in the in the analysis exactly, which includes every rule in Texas hold 'em cash games.

11. Players will only be able to see their pocket cards and the table's community cards

Each player is a member of the tables group socket, which sends pot and player actions and chat messages. Players also have a private socket that sends the players money and cards, and dealer. This way no player can see anyone else's cards.

12. If a player leaves a table, they will automatically fold

When a player leaves the table, they disconnect from the web socket in which their **Players** record is deleted. On their turn, if no record relating to a player is found, it means the player has left and the player is folded.

13. A leader board shows players ranked by their total money

A SQL query is used to get all users usernames and money ordered by their money in descending order. This is then passed to the dynamic template which iterates through each of them adding them to a table to create a static web page. Each record of the table is a CSS button that redirects to the user's profile.

14. Players can interact with each other using an in-table chat

The message is sent over poker web socket in each table. Once the user presses enter, the JavaScript takes the input from the chat box and sends it over the web socket. The algorithm appends <username>: to the front of the message and sends it to the players in the table, who receive it and pass it to the JavaScript which writes it to the top of the chat text box.

a. The chat can be filtered so that swear words would be censored

Once a player joins a table, the web socket reads a censored word file and adds each word to an array. Once a message is received from the user, it checks whether any words in the message are in the censored words array. If so it replaces the word with an appropriate number of asterisks.

15. A how to play page is provided for new players

A static web page is served at the URL how-to-play/ which contains the poker rules from the analysis. This is available to all users and is a static HTML resource.

16. Multiple games on the website can be played at the same time

Each game is running on its own poker thread and has its own **Room** and **Table** record, and each player in the table has a **Players** object, which has a foreign key to the corresponding **Room** they

are in. This system can sustain as many simultaneous poker games as needed up to the servers computing power.

Feedback

Supervisor and end user comments – ***Bold and italic***

Supervisor comments

When I performed my whole system test the overall feedback was positive and I feel like I've made a good base product that meet all the objectives I had for the project. My supervisor commented that it was always clear in a game what was currently happening, and the general UI of the website was clean and intuitive. However, Archie suggested that ***I could use images of cards in the game and animations rather than the cards being text based and that the users could be shown to be sat round the table to easily show the betting order.*** I totally agree with this and these were a few of my extension objectives that I decided not to implement as it would not add much to the complexity of the program.

Archie also suggested that ***the censored words in the text chat could be improved to match all cases and 1337 speak*** (e.g. replacing e with 3), ***and also match even with spacing and punctuation between letters.*** This could also apply to table names. We also found a minor bug where if players go all-in, and after which only 1 player has money left in the table, the river is shown in the poker log but not in the current community cards. This was easily fixed with a moving of a function and was a very minor bug and so after much testing I believe the underlying algorithms and programs are solid.

End user feedback

My end users were 6 other members of my class, aged 17-18, playing on their own computers connected to the web server over local Wi-Fi. I supervised them but let them use the website themselves. They created many different tables and accounts and users played in different tables simultaneously.

Users suggested that there could be a way of ***adding friends on the app, which you could join and play with if they were online.*** They also suggested ***more stats to be shown on the player profile such as games played and best hand as it looks quite bare.***

In the poker game, my end users thought that adding a way to ***see all other players in game and their money*** rather than just the poker log showing what each players action was. This could again be also used to represent the player betting order so players have a better idea on what position they are in the table – which can be extremely important in poker. Also suggested was a ***re buy button so when players run out of money, they are prompted to re buy in the table instead of spectating and having to leave and re-join the table.*** There could also be a spectator feature in each game where you optionally watch the game without buying in.

Improvements

Improvements based on feedback

As stated in my feedback, I could improve the GUI in the poker game by using card and poker chip images and animations, and the players could be shown in a circle around the table to easily show betting order and remove a layer of abstraction to the game. A rebuy button could be shown for

when players run out of money so that they can easily keep playing instead of leaving the table and re-joining.

Users could be given the ability to add friends, in which they can view who is active and join their table if possible, from the 'friends' sidebar. Players could add friends through poker games, visiting their profile, or searching their username in the sidebar. Conversely players can invite their friends to tables. Another feature could be that players could create private tables that are only available to their friends or require a password to enter.

User stats could be added, which would be linked with each user to the stored on the database. For example: hands played, hands won, best hand. If a user visits a profile, they can view the players stats. I could also add a settings page so when a user visits their own profile, they can edit settings on their account, such as changing email and password or turning censored chat on or off.

The chat could also be filtered as mentioned in my feedback.

Other improvements

Use NO-SQL database for Players and Room tables, as they are temporary tables that are written to often, so for scalability if the website had more visitors, a NO-SQL database such as MongoDB would be ideal for these tables to reduce the number of read and writes in the database. The web application could also use HTTPS to secure the communication, which would be essential if it were available on the open internet. While my sign up and log in pages already have CSRF tokens, if I was to make it publicly available, I would need a re-captcha authentication to prevent bots, and using email confirmation to prove accounts are real.

The website could be hosted on the internet through a service such as AWS and purchasing a domain name. This would require some maintenance and the database would have to be migrated from SQLite3 to a more stable system such as PostgreSQL.

Currently, the site is manually tested, which means I manually test that every part of the site works the way it should myself. As the application becomes larger, it becomes increasingly harder to check new updates don't affect other existing parts of the site. Django by default includes the means to write automated tests, these are simply requests or inputs on parts of the website where the correct value is already known. (e.g. giving a hand with a pair to poker algorithm and testing it recognises the pair). This is known as 'unit testing'.

A bet slider could be used to raise instead of a text box to better the user experience. Players could also decide on joining a table whether they want to sit down or spectate the game. A feature could be added that allows players to join multiple tables at once and switch between them.

I could have used a JavaScript framework on the frontend such as Vue.js to make the web app more reactive such as newly created tables showing on the home screen without refreshing. It could also reduce the amount of custom JS I have written.

The backend of the web application already uses Django Rest Framework to serialize table and player data for the frontend. I could use this to create an API that could power other services such as a mobile app.

A poker AI could be developed that users could optionally add to tables to fill player spots. When playing with an AI bot, the user would use temporary money that would not affect their total money they have gained so users cannot exploit the bots.

Instead of using fake money, the website could allow users to bet with real money against other players. However, this would require the website to be regularly and extensively security tested as the website would be storing bank information, which is a much higher security risk and also makes the website a target to hackers. It would also have to comply with government laws and have a system of verifying ID documents to prevent under 18s from using this feature. So realistically this would be extremely hard or impossible to maintain without a larger team and beyond the scope of this project.

how-to-play.html

```

{% extends "base.html" %}
{% block pageContent %}
  <body>
    <div class="container-fluid">
      <div class="col-sm-10 pt-2">
        <h2>How to play</h2><br>
        <h4>Pre-Game</h4>
        <p>
          One player acts as dealer. The dealer is represented by the player with the dealer button, and moves clockwise each round.

          The game starts with two forced bets by the two players to the dealers left. These are called the small blind (SB) and the big blind (BB).

          The SB is equal to the minimum bet. The BB is twice that of the small blind. After the blinds, play moves into the betting phase.
        </p>
        <br>

        <h4>Play</h4>
        <p>
          Following the blinds, each player receives two cards face down. These are your 'hole' cards. The play continues clockwise, where each player following the blinds can either:
        </p>
        <p>
          • Call - Calling matches the highest bet, in this case the BB. If the highest current bet is 0 and the player calls, it is called a 'check'.
        </p>
        <p>
          • Raise - A player can raise the bet up to the amount they have left on the table.
        </p>
        <p>
          • Fold - By folding, a player is choosing not to continue betting and withdraws from the round.
        </p>
        <p>
          The betting round continues until every player has put an equal amount of money in the pot or there is only one player left in the round. If a player calls or raises up to all of their money, they are said to have gone 'all-in', and a side-pot is created, which contains the pot which equates to the amount of chips the player has put in.

          This means that the other players may continue to bet between themselves with the all-in player only eligible to win chips up to the amount he has put in.

          Once the betting round has completed, three community cards are shown, known as 'the flop'. Community cards can be used by any player to make the best 5 card hand possible.
        </p>
      </div>
    </div>
  </body>
{% endblock %}

```

Another betting round then commences where the players have an option to call (or 'check' if no bet has been made), raise (or bet if a bet has been made) or fold. When the second betting round is finished, a fourth card is shown, known as 'the turn'.

Another betting round takes place, after which the final card is shown, known as 'the river' and after the final betting round if there are still two or more players left, the game goes to a showdown.

</p>

<h4>Showdown</h4>

<p>

If a player bets and all other players fold, the player is awarded the pot and is not required to show his cards. However, if there are still two or more players left after the final round of betting, a 'showdown' occurs, where the last player to bet is the first to show his hand, unless everyone checks in which case the player to the left of the dealer button is the first to show.

After the first player has shown his cards, the players must show their cards in a clockwise rotation if they can beat the best players hand to show. Otherwise they can choose not to show, and 'muck' their losing hand without showing them.

If two players have the same hand strength, 'kickers' can be used to break ties. These are extra cards that do not add to the rank of the hand.

For example K-K-10-3-2 would beat K-K-9-8-7 even though they are both pairs of kings, as the 10 would beat the 9. If the best hand is shared by two or more players, the pot is shared between them. If the pot cannot be equally distributed among all the players in the split pot, the odd chips are given precedence to the winners that are first to play.
